To study a multirate system, each subsystem can be solved by a dedicated software with respect to the physical problem and the time constant. Then, the problem is the coupling of the solutions of the subsystems. The Waveform Relaxation Method (WRM) seems to be an interesting solution for the coupling but until now it has been mainly applied on academic examples. In this paper, the WRM is applied to perform the coupling of a controlled rectifier and a non-linear finite element model of a transformer.

Index Terms—Waveform relaxation method, multirate system, multi-physics and coupled problems, finite element method.

I. INTRODUCTION

AN electrical system can involve several devices with different physics and dynamics. The simulation in the time domain of such a set of devices can be carried out by coupling numerical models that is to say a system of Differential Algebraic Equations (DAE).

A direct strong coupling consists in gathering the DAE systems and to solve them at the same time. With an indirect strong coupling, each DAE system is solved successively until convergence at each time step. But in both cases, the time-step must be chosen according to the smallest time constant. This can lead to an expensive computation time if some DAE systems have a large number of unknowns like in the case of Finite Element Model (FEM). A first alternative can be the weak coupling of the DAE systems with different time-steps, but the consistency of the coupling is most of the time not assured. A second alternative is to reduce the FEM using a surface response technique [1]. The issue is then to control the accuracy of the reduced model.

The Waveform Relaxation Method (WRM) [2] allows a consistent coupling to solve this kind of problem. The WRM approach is an iterative process which converges in theory to the solution of a strong coupling [3]. The method was used for many years for the simulation of circuits [4], [5] or transmission lines [6], and has been recently studied for the coupling of circuit equations and a FEM [7], [8], either by source coupling or by parameter coupling [9], [10].

In this paper, we propose to study the parameter coupling of a FEM to circuit equations including a control loop. First, the WRM is briefly described. Then, the interest and the basic principle of the method is brought out on academic example. Afterwards, a more elaborate WRM approach is applied to study a more realistic and complex system involving a control loop, a single phase transformer associated with a controlled rectifier. The transformer is modeled by a non-linear FEM and the rectifier is controlled by a Pulse Width Modulation (PWM) technique, each subsystem being studied with a time-step adapted to its time constant. We use the parameter coupling

WRM to allow not only the coupling between the rectifier and the FEM, but also the control of the current into the FEM.

II. WAVEFORM RELAXATION METHOD

Let consider a system composed of r subsystems, each subsystem i satisfying the DAE

$$\dot{\mathbf{y}}_i(t) = \mathbf{f}_i(\mathbf{y}(t), \mathbf{z}(t)) \quad (1)$$

$$0 = \mathbf{g}_i(\mathbf{y}(t), \mathbf{z}(t)), \quad (2)$$

with $t \in [0, T]$ and the initial conditions $\mathbf{y}(0) = \mathbf{y}_0$ and $\mathbf{z}(0) = \mathbf{z}_0$, \mathbf{y} being the differential variables and \mathbf{z} the algebraic variables. The WRM computes iteratively an approximation ($\tilde{\mathbf{y}}^k(t)$, $\tilde{\mathbf{z}}^k(t)$) of the exact solution. The first step is the extrapolation step: for $k = 0$, $\tilde{\mathbf{y}}^k(t) = \mathbf{y}_0$, $\tilde{\mathbf{z}}^k(t) = \mathbf{z}_0$, $\forall t \in [0, T]$. Then at the iteration k and for the subsystem i , the algorithm solves

$$\dot{\tilde{\mathbf{y}}}_i^k(t) = \mathbf{f}_i(\mathbf{Y}_i^k(t), \mathbf{Z}_i^k(t)) \quad (3)$$

$$0 = \mathbf{g}_i(\mathbf{Y}_i^k(t), \mathbf{Z}_i^k(t)). \quad (4)$$

The value of \mathbf{Y}_i^k (resp. \mathbf{Z}_i^k) depends on $\tilde{\mathbf{y}}^{k-1}$ and $\tilde{\mathbf{y}}^k$ (resp. $\tilde{\mathbf{z}}^{k-1}$ and $\tilde{\mathbf{z}}^k$) and on the relaxation schemes (Picard, Jacobi or Gauss-Seidel). For example, with the Gauss-Seidel scheme, the subsystems are solved sequentially with $\mathbf{Y}_i^k(t) = [\tilde{\mathbf{y}}_1^k, \dots, \tilde{\mathbf{y}}_{i-1}^k, \tilde{\mathbf{y}}_i^k, \tilde{\mathbf{y}}_{i+1}^{k-1}, \dots, \tilde{\mathbf{y}}_r^{k-1}]^T$, and $\mathbf{Z}_i^k(t) = [\tilde{\mathbf{z}}_1^k, \dots, \tilde{\mathbf{z}}_{i-1}^k, \tilde{\mathbf{z}}_i^k, \tilde{\mathbf{z}}_{i+1}^{k-1}, \dots, \tilde{\mathbf{z}}_r^{k-1}]^T$.

Subsystems are solved on the overall time domain $[0, T]$, then the waveforms are transferred from one subsystem to the others. Consequently, each subsystem can be solved with respect to its own time-step. Since the waveforms \mathbf{y}_i and \mathbf{z}_i of each subsystem are sampled with different time-steps, interpolation technics are required to reconstruct a waveform consistent with the other time steps.

III. ACADEMIC PROBLEM

To introduce the problematic of the targeted applications and the interests of the WRM, we consider the coupling of a LC filter with a transformer. The LC filter contains a PWM voltage

source and supplies the transformer with a filtered voltage. To simulate such a device, a very small time-step is necessary to deal with the PWM. As the amplitude of high order harmonics of the voltage applied to the transformer are very small due to the LC filter, the time-step could be larger for this part of the device. If a finite element model of the transformer is considered with the smallest time-step, the computation time can be extremely high. A strong coupling is so inappropriate in this case. On the contrary, the waveform relaxation approach seems well-adapted to simulate the device since a time-step adapted to each subsystem can be used.

Fig. 1. Strong coupling and WRM models of the device.

The PWM voltage source has a 50 Hz fundamental frequency and a 20 kHz switching frequency. As a first step, the model in Fig. 1(a) is solved with a strong coupling by a FEM. The resulting voltage and currents are presented in Fig. 2 to 4. The current i_R appears to be a smooth and regular waveform with a 50 Hz frequency.

As a second step, the device is split in two subsystems with the LC filter on one hand, the FEM on the other hand (Fig. 1(b)). The LC circuit is simulated with a time-step adapted to the PWM (2.10^{-7} s), and the FEM with a time-step 500 times larger. The coupling is done by supplying the primary coil of the transformer by the interpolated voltage v_c from the circuit; then the current i_R in the winding is interpolated and imposed to the circuit as a source. This kind of WRM is called source coupling. The interpolation is a simple linear interpolation between two points.

The results plotted on the same Fig. 2 to 4 show quite good similarity. The introduction of a coarse time-stepping for the transformer and of the interpolation leads to a waste of precision. Nevertheless, the error indicated in Table I are really weak. Then, after 6 WRM iterations, the error is less than 1.23%. The convergence of the process is very fast, as it can be seen on Fig. 5: after 6 iterations, the criterion convergence is less than 10^{-7} . The most important information to notice is that the computation time to simulate only one period is very long with the strong coupling. Several weeks are needed to obtain results, whereas with the WRM the results are available in several hours (Table I).

Fig. 2. Voltage v_c .

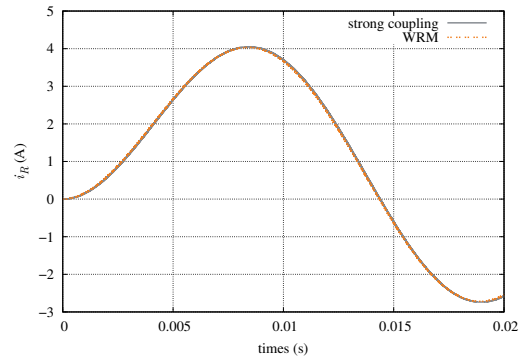

Fig. 3. Current i_R .

Fig. 4. Current i_L .

Fig. 5. Convergence criterion of the WRM.

The computation time is considerably reduced with the WRM because the number of arithmetic operations itself is reduced compared to a strong coupling. We call n_{u1} (respectively n_{u2}) the number of unknowns of the FE problem (resp. the circuit problem) and n_{t1} (respectively n_{t2}) the number of time-steps of the FE problem (resp. the circuit problem). The conjugate gradient (CG) is used to solve the matrix system of the FE problem. The complexity of the CG, including convergence, is in $\mathcal{O}(n_{u1}^3)$ for a full matrix ($\mathcal{O}(n_{u1}^2)$ per iteration with a convergence in n_{u1} iterations at the most) or $\mathcal{O}(n_{u1}^\alpha)$, $\alpha < 2$ for a sparse matrix. In our problem, $n_{u1} \gg n_{u2}$ and $n_{t2} \gg n_{t1}$, so we can consider a complexity of $\mathcal{O}(n_{t2}n_{u1}^\alpha)$ for a strong coupling and $\mathcal{O}(Kn_{t1}n_{u1}^\alpha)$ for a WRM coupling, with K the maximum number of WRM iterations. As $n_{t2} \gg n_{t1}$, in most of the case, $n_{t2} > Kn_{t1}$ and so the computation time could be reduced.

TABLE I
COMPUTATION TIME, COMPLEXITY AND ERRORS FOR 6 WRM ITERATIONS

	Strong coupling	WRM coupling
Computation time	13 days 7h8min	2h40min
Error on i_R	-	1.13%
Error on v_c	-	0.67%

IV. INDUSTRIAL APPLICATION

The WRM is applied to study a more complex device. Let us consider a transformer and its associated rectifier as in Fig. 6. The rectifier is controlled to provide a direct voltage v_{dc} of 800 V and a current i_s into the secondary winding in phase with the voltage v_{20} ; moreover, a current i_{ch} is imposed into the rectifier circuit as a load current. The control based on a PWM requires a very small time-step $\Delta t_r = 5 \cdot 10^{-6}$ s. The transformer is modeled by a FE method with a magnetic vector potential formulation. This model is non-linear: the reluctivity depends on the magnetic field. The voltages v_{10} and v_s are respectively imposed to the primary and secondary windings. The solution of the FEM using the time-step Δt_r is unaffordable in terms of computation time. The WRM allows to use a larger time-step allowing to drastically reduce the computation time.

Fig. 6. Complete device of the traction transformer

The WRM is applied to perform the coupling between the FEM of the transformer and the circuit model of the rectifier. A classic source coupling, as the one used in the previous section, does not allow to control the current i_s into the secondary winding because it would be imposed as a source to the circuit rectifier part. Therefore, a parameter coupling is used [9], [10]. An equivalent circuit of the transformer is introduced into the rectifier circuit (Fig.7) with a resistance R and an inductance L . The resistance is the same than in the FEM, and the inductance is obtained by a calculation based on a linear FEM of the transformer. Then, a residual current source i_{res} is added (Fig. 7) to guarantee the consistency of the coupling. The non-linear effects of the transformer are introduced into the electrical circuit by the residual current, without any change in the equivalent model.

At the k^{th} iteration of the WRM process, the source of the FEM is the voltage v_s^k , and its solution provides the current i_s^k in the secondary winding. The voltage v_s^k is given by the solution of the electrical circuit model composed of the equivalent circuit of the transformer and the controlled rectifier. In this model, the residual current i_{res}^k is a source; the voltage v_{dc}^k is controlled to be equal to 800 V and the current i_2^k is also controlled to be in phase with the voltage v_{20} . The residual current is such that $i_{res}^k = i_s^{k-1} - i_L^{k-1}$. Over the iterations of the WRM process, the current i_s^k converges to i_2^k . At the end of the process, i_s^k is in phase with the voltage v_{20} . Fig. 8 presents the convergence criterion related to the current i_s of the WRM process. The convergence is less clear compared to the academic example. Nevertheless, the WRM gives solutions relatively stable. According to the parameter coupling, the current i_s^k tends to be in phase with the voltage v_{20} (Fig. 9). Furthermore, Fig. 11 shows that the voltage v_{dc} is close to 800 V. Fig. 10 shows the current i_p into the primary winding for non-linear FEM.

To compute this simulation on a time interval of 2 seconds, 3 days 9 hours 31 minutes are needed to perform 4 WRM iterations, but 99.81% of the computation time is dedicated to solve the FEM. This should be compared with the 3 months estimated to perform the simulation using the same time step for the control loop and the FEM. The WRM converges to the exact solution as proved in [9], so the solution is supposed to be close to the exact one.

V. CONCLUSION

The WRM is well-adapted to the coupling and the simulation of multirate systems because it allows to use a time discretisation per subsystem.. A first application presented the source coupling approach on an academic case. Comparisons with a strong coupling showed small errors and a speed up of 120. A second application showed the interest of the parameter coupling for control the current in a non-linear FEM coupled to a rectifier.
