ABSTRACT

Bensa *et al.* [*J. Acoust. Soc. Am.* **114**(2) 1095–1107 (2003), Section IV] recently proposed a waveguide model for the transverse displacement of a stiff piano string. The study described here is an attempt to cast a complementary light on this topic, based on a common *wave approach* instead of a *modal approach*. A pair of weakly attenuated traveling waves and a pair of fast-decaying waves both satisfy the one-dimensional wave equation developed by Bensa *et al.*. These solutions have to be carefully considered, however, for portions of string interacting with the hammer felt, the bridge, or the *capo d'astro* bar.

PACS number: 43.75.Mn

I. INTRODUCTION

The first attempt for synthesizing musical sounds using physical models was made more than 30 years ago by Hiller and Ruiz¹. Starting from the *one-dimensional wave equation*² of the transverse displacement of a string, three main approaches are generally used for building a computational model: either the use of a finite difference scheme (*e.g.* Refs. 3, 4), or a modal synthesis (*e.g.* Ref. 5), or the building of a *Digital Waveguide* model (*e.g.* Refs. 6, 7, 3). A *waveguide* is considered here as a “*filterlike structure modeling one-dimensional wave propagation as purely lossless throughout the length of the string, with loss and dispersion lumped in terminating filters*”³. The hammer action and the reflection conditions at both ends of the string are also modeled as *lumped* filters. Portions of string are *distributed* elements⁶ represented by two-port networks. In this paper we focus on this latter approach.

Bensa *et al.* propose an improved *one-dimensional wave equation* [Ref. 3, Eq. (6)] corresponding to a *well posed* model of stiff piano strings. In Sec. IV.B they use a *modal approach* to extract the waveguide parameters from the partial differential equation (PDE). This approach requires the knowledge of both the length of the string and the boundary conditions [Ref. 3, Eq. (10)] for the calculation of the vibration modes associated with standing waves. The waveguide parameters are then deduced from the characteristics of the first mode including the fundamental frequency of the ideal string. The present paper is an attempt to show that a *wave approach* using complex wave-numbers appears as more convenient because each dispersive attenuated traveling wave is directly obtained from the one-dimensional wave equation, apart from the reflections at the ends of the string. Assuming that the one-dimensional wave equation is linear, time- and space-invariant, a two-dimensional Fourier-Laplace transformation gives an algebraic equation relating the transverse displacement of the string (output) to the space distribution of external forces (input) in the *wave-number/frequency* domain. The solution of this equation can be seen as the superposition of traveling waves which occur in a waveguide model.

Some general points about waveguides, traveling waves, and complex wave-numbers are outlined in Section II to help the reader to understand the following sections. In Section III, after the one-dimensional wave equation advanced by Bensa *et al.*³ is recalled, this equation is solved to obtain the response of an infinite string to a point impulse in the *wave-number/frequency* domain, showing that two fast-decaying traveling waves are omitted by the modal approach in Bensa *et al.*³. These fast-decaying waves can be neglected only for portions of string without sources which are long enough. They should, however, be taken into account at the neighborhood of the excitation point, as detailed in Section IV.

II. WAVEGUIDE MODELING AND COMPLEX WAVE-NUMBERS

The question is this: how to pass from the wave equation of a one-dimensional system to a *waveguide* model?

A. From the one-dimensional wave equation to the transfer function

1. A general one-dimensional wave equation

The vibration state of a one-dimensional system (*e.g.* the stiff piano string) is assumed to be defined by a function y (*e.g.* the transverse displacement of the string) of time t and position x along the system.

A general one-dimensional wave equation, assuming that it is linear, time- and space-invariant, can be written as:

$$\sum_{m=0}^{d_x} \sum_{n=0}^{d_t} \alpha_{m,n} \frac{\partial^{m+n} y}{\partial x^m \partial t^n}(x, t) = f(x, t), \quad (1)$$

where f is the space distribution of external forces (*e.g.* exerted by the hammer felt, the bridge and the *capo d'astro* bar).

2. Time/frequency and space/wave-number conversions

In the *space/frequency* domain, each signal $s(x, t)$ is converted into $\widehat{s}(x, \omega)$ by Fourier transformation:

$$\widehat{s}(x, \omega) = \int_{-\infty}^{+\infty} s(x, t) e^{-i\omega t} dt, \quad (2)$$

where ω is the angular frequency and $i^2 = -1$.

In the *wave-number/frequency* domain, each signal $s(x, t)$ becomes $S(k, \omega)$ by Fourier–Laplace transformation:

$$S(k, \omega) = \int_{-\infty}^{+\infty} \widehat{s}(x, \omega) e^{-ikx} dx = \int_{-\infty}^{+\infty} \int_{-\infty}^{+\infty} s(x, t) e^{-i(\omega t + kx)} dt dx, \quad (3)$$

where k is the complex wave-number.

3. An ordinary differential equation in the *space/frequency* domain

The Fourier transformation of the wave equation (1) leads to an ordinary linear constant-coefficient differential equation with respect to x :

$$\sum_{m=0}^{d_x} \left[\sum_{n=0}^{d_t} \alpha_{m,n} (i\omega)^n \right] \frac{\partial^m \widehat{y}}{\partial x^m}(x, \omega) = \widehat{f}(x, \omega). \quad (4)$$

4. The transfer function

In the *wave-number/frequency* domain, we obtain:

$$\left[\sum_{m=0}^{d_x} \sum_{n=0}^{d_t} \alpha_{m,n} i^{m+n} \omega^n k^m \right] Y(k, \omega) = F(k, \omega) \iff Y(k, \omega) = H(k, \omega) F(k, \omega), \quad (5)$$

where $H(k, \omega)$ is the transfer function of the system. The denominator of $H(k, \omega)$ is a polynomial of order d_x in k and order d_t in ω . The poles of $H(k, \omega)$ (where $H(k, \omega)$ is considered as a function of k) are the roots of a polynomial equation commonly called the *dispersion equation*.

B. From the transfer function to the block-diagram model

1. The impulse response as the sum of pairs of symmetrical traveling waves

Assuming both that the propagation model corresponds to a well-posed physical problem (*cf. e.g.* Ref. 3 for more details) and that the problem is symmetrical (*i.e.*, unchanged by substituting $-x$ for x), the coefficients $\alpha_{2k+1,n}$ are zero, which implies that $d_x = 2J$ is an even number, and the transfer function $H(k, \omega)$ is rewritten as follows:

$$H(k, \omega) = \frac{a(\omega)}{\prod_{j=1}^J [k^2 - k_j(\omega)^2]} = \sum_{j=1}^J \frac{a_j(\omega)}{k^2 - k_j(\omega)^2} = \sum_{j=1}^J g_j(\omega) \left[\frac{1}{k - k_j(\omega)} - \frac{1}{k + k_j(\omega)} \right], \quad (6)$$

where $a_j(\omega) = a(\omega) / \prod_{m=1, m \neq j}^J [k_m(\omega)^2 - k_j(\omega)^2]$ and $g_j(\omega) = a_j(\omega) / [2k_j(\omega)]$, assuming $k_j(\omega) \neq 0$ and $k_j(\omega) \neq k_m(\omega)$ if $j \neq m$.

For an infinite system, the assumed boundary (no sources at infinity) and initial conditions (rest initial condition) are:

$$y|_{x \rightarrow +\infty} = y|_{x \rightarrow -\infty} = 0; \quad y|_{t < 0} = 0; \quad \forall n, 1 \leq n \leq d_t - 1, \quad \left. \frac{\partial^n y}{\partial t^n} \right|_{t < 0} = 0. \quad (7)$$

Coming back to the *space/frequency* domain, Eqs. (6) and (7) lead to the convolution product with respect to the spatial variable:

$$\hat{y}(x, \omega) = \int_{-\infty}^{+\infty} \hat{f}(x_0, \omega) \hat{h}(x - x_0, \omega) dx_0, \quad (8)$$

$\hat{h}(x, \omega)$ satisfying

$$\hat{h}(x, \omega) = \sum_{j=1}^J g_j(\omega) [e^{-i k_j(\omega) x} u(x) + e^{+i k_j(\omega) x} u(-x)], \quad (9)$$

where u is the Heaviside unit step function:

$$\forall x < 0, u(x) = 0 \text{ and } \forall x \geq 0, u(x) = 1.$$

The function $\hat{h}(x, \omega)$ corresponds to the Fourier transform of the impulse response $h(x, t)$ (also named Green's function) to $f(x, t) = \delta(x) \delta(t)$ where δ is the Dirac impulse. This response $h(x, t)$ is the effect of a time impulse (at $t = 0$) exerted on a single point (at $x = 0$) of the system. The unit of h is the unit of y per Newton and per second. An inverse Fourier transformation gives:

$$h(x, t) = \frac{1}{2\pi} \sum_{j=1}^J \int_{-\infty}^{+\infty} g_j(\omega) \{e^{i[\omega t - k_j(\omega) x]} u(x) + e^{i[\omega t + k_j(\omega) x]} u(-x)\} d\omega. \quad (10)$$

Note that $h(x, t) = h(-x, t)$: the symmetry of the problem is satisfied.

Each $k_j(\omega)$ is a complex wave-number such that:

$$k_j(\omega) = \omega \tau_j(\omega) - i \alpha_j(\omega) = \frac{\omega}{c_j(\omega)} - i \alpha_j(\omega), \quad (11)$$

where $\tau_j(\omega) \geq 0$ is the propagation delay per unit length (or slowness), $c_j(\omega)$ the phase velocity, and $\alpha_j(\omega) \geq 0$ the attenuation per unit length.

The impulse response can be rewritten as:

$$h(x, t) = \frac{1}{2\pi} \sum_{j=1}^J \int_{-\infty}^{+\infty} g_j(\omega) \{e^{-\alpha_j(\omega) x} e^{i\omega [t - x/c_j(\omega)]} u(x) + e^{+\alpha_j(\omega) x} e^{i\omega [t + x/c_j(\omega)]} u(-x)\} d\omega. \quad (12)$$

This impulse response is consequently the superposition of J pairs of symmetrical decaying traveling waves starting from the excitation point and propagating in opposite directions.

Thus, the general solution y is given by the two-dimensional convolution:

$$y(x, t) = \int_{-\infty}^{+\infty} \int_{-\infty}^{+\infty} f(x_0, t_0) h(x - x_0, t - t_0) dx_0 dt_0. \quad (13)$$

2. Waveguide modeling of a region without sources

Under the assumption that no sources exist in a region between $x = x_{\min}$ and $x = x_{\max}$, one can demonstrate that the vibration state is the sum of J decaying traveling waves y_j^+ in the increasing x direction and of J decaying traveling waves y_j^- in the decreasing x direction:

$$\forall x, x_{\min} \leq x \leq x_{\max}, \quad y(x, t) = \sum_{j=1}^J y_j^+(x, t) + \sum_{j=1}^J y_j^-(x, t), \quad (14)$$

where $\widehat{y}_j^+(x, \omega) = e^{-i k_j(\omega)(x-x_{\min})} \widehat{y}_j^+(x_{\min}, \omega)$
and $\widehat{y}_j^-(x, \omega) = e^{+i k_j(\omega)(x-x_{\max})} \widehat{y}_j^-(x_{\max}, \omega)$.

This region can be modeled as J waveguides in parallel which become J *digital waveguides*^{e.g.6,7} in discrete time. Each transfer function $e^{-i k_j(\omega) \Delta x}$ is generally designed as a delay line in series with a digital causal filter. After suitable digital filters have been found, efficient time-domain simulations can be made.

In the case of piano strings, the sources are located in the segment of hammer felt/string contact and at both ends. A block-diagram model is drawn in Fig. 1, including an observation point. This figure is a generalization of the model involved in Bensa *et al.* (Ref. 3, Fig. 2). Note that the boundary conditions characterizing the string terminations can be changed by only modifying one lumped filter at each end, apart from the waveguides modeling the portions of string without sources.

Figure 1: Block-diagram of the waveguide model of a piano string. The string segment interacting with the hammer felt is assumed to be $[x_0 - \delta x ; x_0 + \delta x]$. x_1 is the position of observation. $x = 0$ is the *capo d'astro* bar position and $x = L$

is the bridge position. Each $H_n(\omega)$ is equivalent to J delay line/filter blocks in parallel: $H_1(\omega) = \sum_{j=1}^J e^{-i k_j(\omega)(x_0 - \delta x)}$,

$$H_2(\omega) = \sum_{j=1}^J e^{-i k_j(\omega)(x_1 - x_0 - \delta x)} \quad \text{and} \quad H_3(\omega) = \sum_{j=1}^J e^{-i k_j(\omega)(L - x_1)}.$$

III. THE FOUR WAVES IN A STIFF PIANO STRING

In this section and the next one, we apply the principles given in the previous section to the one-dimensional wave equation introduced by Bensa *et al.* [Ref. 3, Eq. (6)]. The dispersion equation provides two pairs of decaying traveling waves which need a detailed analysis.

A. The transfer function of a stiff piano string

The transverse displacement y is assumed to satisfy [Ref. 3, Eq. (6)]:

$$\frac{\partial^2 y}{\partial t^2} + 2b_1 \frac{\partial y}{\partial t} - 2b_2 \frac{\partial^3 y}{\partial x^2 \partial t} - c^2 \frac{\partial^2 y}{\partial x^2} + \kappa^2 \frac{\partial^4 y}{\partial x^4} = \frac{1}{\mu} f, \quad (15)$$

where b_1 is the first coefficient of damping (due to viscosity of the air), b_2 the second damping coefficient (inner losses), $c = \sqrt{T/\mu}$ the transverse wave velocity of string⁴, T the string tension, μ the linear mass density of string, $\kappa = c \sqrt{EI/T}$ a stiffness coefficient, E the Young modulus, $I = Sr^2$ the moment of inertia of the cross-section, S the cross-section, and r the radius of gyration.

In the *wave-number/frequency* domain, Eqs. (5) and (15) lead to the transfer function:

$$H(k, \omega) = \frac{Y(k, \omega)}{F(k, \omega)} = \frac{1}{\mu [(-\omega^2 + 2i\omega b_1) + (c^2 + 2i\omega b_2)k^2 + \kappa^2 k^4]}. \quad (16)$$

B. Complex wave-numbers

The two ($J = 2$) wave-numbers k_s and k_d satisfy:

$$k_s^2(\omega) = \frac{c^2}{2\kappa^2} \left[-1 - i \frac{2\omega}{c^2} b_2 + \sqrt{1 + \frac{4(\kappa^2 - b_2^2)\omega^2}{c^4} + 4i\omega \left(\frac{1}{c^2} b_2 - 2 \frac{\kappa^2}{c^4} b_1 \right)} \right], \quad (17)$$

$$k_d^2(\omega) = \frac{c^2}{2\kappa^2} \left[-1 - i \frac{2\omega}{c^2} b_2 - \sqrt{1 + \frac{4(\kappa^2 - b_2^2)\omega^2}{c^4} + 4i\omega \left(\frac{1}{c^2} b_2 - 2 \frac{\kappa^2}{c^4} b_1 \right)} \right]. \quad (18)$$

These equations are similar to Eq. (11) in Ref. 3. The approaches, however, are different. In the modal approach³ β_+ and β_- are real-valued functions of the complex frequency s . In the present wave approach k_s and k_d are the roots of the *dispersion equation* and are complex-valued functions of the common angular frequency ω (real number).

The assumptions [Ref. 3 Eqs. (24) and (25)]

$$b_1 b_2 \ll c^2; \quad b_2^2 \ll \kappa^2 \text{ and } b_1^2 \ll \omega^2 \quad (19)$$

lead to

$$k_s(\omega) \simeq \frac{c}{\kappa} \sqrt{\frac{\xi}{2}} - i \frac{\kappa \omega}{c^3 (1 + \xi)} \sqrt{\frac{2}{\xi}} \left(b_1 + \frac{c^2 \xi}{2\kappa^2} b_2 \right) \quad (20)$$

and

$$k_d(\omega) \simeq \frac{1}{c^3 \sqrt{2\xi} (1 + \xi)} (2\omega^2 b_2 - c^2 \xi b_1) - i \sqrt{\frac{2}{\xi}} \frac{\omega}{c}, \quad (21)$$

with

$$\xi = -1 + \sqrt{1 + \frac{4\kappa^2}{c^4} \omega^2}. \quad (22)$$

C. Waveguide modeling of portions of string without sources

The first wave-number k_s characterizes a weakly attenuated dispersive traveling wave similar to the one described by Bensa *et al.* [Ref. 3, Eq. (34)]. At low frequencies [$b_1^2 \ll \omega^2 \ll c^4/(4\kappa^2)$] the phase velocity is close to c . Its numerical values are between 160 and $420 \text{ m} \cdot \text{s}^{-1}$ for piano tones C2, C4, and C7 (Ref. 3, Table I). The attenuation per unit length $\alpha_s \simeq b_1/c$ is small : its numerical values [$10 \alpha_s / \log(10)$] are less than $0.1 \text{ dB} \cdot \text{m}^{-1}$.

The second wave-number k_d represents a fast-decaying wave with a very high phase velocity. At low frequencies the phase velocity is approximately $c\kappa/(b_2 - \kappa^2 b_1/c^2)$. Its numerical values are in the range 2.6×10^5 to $1.62 \times 10^6 \text{ m} \cdot \text{s}^{-1}$. The attenuation per unit length is $\alpha_d \simeq c/\kappa$. The numerical values [$10 \alpha_d / \log(10)$] of α_d are greater than $1.1 \times 10^3 \text{ dB} \cdot \text{m}^{-1}$. For any length Δx greater than 1.8 cm , $e^{-\alpha_d \Delta x}$ (the modulus of $e^{-i k_d \Delta x}$) is less than 10^{-2} . This second wave is *quasi-evanescent i.e.*, its phase velocity is almost infinite and its attenuation per unit length is high. It could represent the fact that a part of the energy of a hammer strike would instantly propagate along the stiff string around the contact region such as to avoid the formation of a sharp corner, as shown below and in accordance with Cremer⁸.

Consequently, the waveguide model of a portion of string without sources will contain only a single delay line/filter (wave-number k_s) for each direction of propagation, provided that the portion of string is longer than a few centimeters. But the other wave characterized by k_d cannot be neglected at the neighborhood of the excitation region, as shown in the following section.

IV. The impulse response of the string

A. Space/frequency domain

In the space/frequency domain Eqs. (16–18), (6), and (9) imply that the Fourier transform of the impulse response is:

$$\widehat{h}(x, \omega) = \begin{cases} \widehat{h}_s^+(0, \omega) e^{-i k_s(\omega) x} + \widehat{h}_d^+(0, \omega) e^{-i k_d(\omega) x} & x > 0 \\ \widehat{h}_s^+(0, \omega) + \widehat{h}_s^-(0, \omega) + \widehat{h}_d^+(0, \omega) + \widehat{h}_d^-(0, \omega) & x = 0 \\ \widehat{h}_s^-(0, \omega) e^{+i k_s(\omega) x} + \widehat{h}_d^-(0, \omega) e^{+i k_d(\omega) x} & x < 0 \end{cases}, \quad (23)$$

where

$$\begin{aligned} \widehat{h}_s^+(0, \omega) = \widehat{h}_s^-(0, \omega) = g_s(\omega) &= \frac{-i}{2 \mu \kappa^2 [k_s(\omega)^2 - k_d(\omega)^2] k_s(\omega)} \\ \widehat{h}_d^+(0, \omega) = \widehat{h}_d^-(0, \omega) = g_d(\omega) &= \frac{i}{2 \mu \kappa^2 [k_s(\omega)^2 - k_d(\omega)^2] k_d(\omega)} \end{aligned}. \quad (24)$$

The complex compliances $g_s(\omega)$ and $g_d(\omega)$ (unit: $\text{m} \cdot \text{N}^{-1}$) characterize the conversion of force to motion.

B. Example of a C2 piano string

The response y of a C2 piano string (Ref. 3, Table I) to a downward Gaussian time impulse at a single point $x = 0$ is given by Fig. 2. This response is very close to the negative of the impulse response h in the bandwidth $0\text{--}20 \text{ kHz}$. The transverse displacement y is the sum of two weakly attenuated traveling waves y_s^\pm (wave-numbers $\pm k_s$) and of two fast-decaying waves y_d^\pm (wave-numbers $\pm k_d$) going away symmetrically from the excitation point. In agreement with Refs. 8 and 2 (Section 2.18), “*the bend is rounded appreciably by the stiffness of the string*”. The fast-decaying waves inhibit the sharp corner which could be generated by the weakly attenuated traveling waves, if the former were not considered. As shown in the previous section, only the weakly attenuated traveling waves exist far from the excitation point (more than 2 cm), as well as in the neighborhood of the excitation point after 0.1 ms .

Figure 2: Response of a C2 piano string to a downward Gaussian impulse f . $f(x, t) = f_0 \delta(x) \varphi(t)$ where $\varphi(t) = -\lambda e^{-\pi \lambda^2 (t-\tau)^2}$. $f_0 = 1 \text{ N}$, $\lambda = 2 \times 10^5 \text{ s}^{-1}$, and $\tau = 0.02 \text{ ms}$. The parameters of the C2 piano string are (Ref. 3, Table I): $c = 160.9 \text{ m} \cdot \text{s}^{-1}$, $\kappa = 0.58 \text{ m}^2 \cdot \text{s}^{-1}$, $b_1 = 0.25 \text{ s}^{-1}$, and $b_2 = 7.5 \times 10^{-5} \text{ m}^2 \cdot \text{s}^{-1}$. The response y (plain line) is the sum of a weakly attenuated wave y_s (dashed line) and of a quasi-evanescent wave y_d (dotted line).

C. Non-causal components of the causal impulse response

An important additional point is that y_s^\pm and y_d^\pm are not causal responses whereas their sum is causal. A mathematical explanation can be found for this by focusing on the impulse response at the excitation point [Eq. (24)]. The signals $h_s^\pm(0, t)$ and $h_d^\pm(0, t)$ and the modulus of their Fourier transforms $g_s(\omega) = \widehat{h_s^\pm}(0, \omega)$ and $g_d(\omega) = \widehat{h_d^\pm}(0, \omega)$ are plotted in Fig. 3 (in the case of a C2 piano string). The latter signal $h_d^\pm(0, t)$ is nearly an even function (with respect to t). The former signal $h_s^\pm(0, t)$ is nearly the sum of a constant $[1/(4\mu c)]$ and of an odd function.

Figure 3: (a) Impulse responses of a C2 piano string and (b) the modulus of their Fourier transforms times the angular frequency. The compliance $g_s(\omega) = \widehat{h}_s^{\pm}(0, \omega)$ is the Fourier transform of the signal $h_s^{\pm}(0, t)$ (weakly attenuated waves, dashed line). $g_d(\omega) = \widehat{h}_d^{\pm}(0, \omega)$ is the Fourier transform of $h_d^{\pm}(0, t)$ (quasi-evanescent waves, dotted line). The impulse response $h(0, t)$ (plain line) is two times the sum of $h_s^{\pm}(0, t)$ and $h_d^{\pm}(0, t)$. Its Fourier transform is $\widehat{h}(0, \omega) = 2[g_s(\omega) + g_d(\omega)]$.

This is natural because, on assuming that b_1 and b_2 are zero, and ω is greater than zero [see Eqs. (17), (18), (22), and (24)], the compliances become:

$$g_s(\omega) \simeq \frac{i\kappa}{\mu c^3 \sqrt{2\xi}(1+\xi)} \quad \text{and} \quad g_d(\omega) \simeq \frac{-\sqrt{\xi}}{2\mu\sqrt{2}c(1+\xi)\omega}. \quad (25)$$

Consequently, the compliance g_s is an imaginary-valued function and g_d is a real-valued function. Because the signals $h_s^{\pm}(0, t)$ and $h_d^{\pm}(0, t)$ are real-valued, the former should be an odd function and the latter an even function. But the Fourier transform of $h_s^{\pm}(0, t)$ has a singularity at $\omega = 0$ and the limit of $h_s^{\pm}(0, t)$, when t tends to $-\infty$, has to be zero. This implies that a constant has to be added to $h_s^{\pm}(0, t)$, giving an additional term $\pi\delta(\omega)/(2\mu c)$ in its Fourier transform.

Applying the final value theorem to the signal $h_s^{\pm}(0, t)$, the limit of $h_s^{\pm}(0, t)$ with t tending to infinity is $1/(2\mu c)$ (see Fig. 3). The final value of the impulse response $h(0, t)$ is similarly $1/(\mu c)$. This last property is false if $b_1 > 0$: all the signals tend slowly to zero when t tends to infinity. Indeed, $h_d^{\pm}(0, t)$ is close to zero for great values of t and $h(0, t) \simeq h_s^+(0, t) + h_s^-(0, t)$.

In summary, the two waves h_s^{\pm} and h_d^{\pm} have to be considered together at the position $x = 0$ to avoid non-physical effects with respect to time. The conversion of force to motion is characterized by a single compliance $\widehat{h}(0, \omega) = 2[g_s(\omega) + g_d(\omega)]$, which is plotted in Fig. 3.

Figure 4: Block-diagram of a portion of string excited by a point force. This force $\varphi(t)$ is exerted by the hammer felt at the position $x = x_0$. The force distribution is assumed to be $f(x, t) = \varphi(t) \delta(x - x_0)$ for x in the range $x_0 - L$ to $x_0 + L'$ (L and L' are both greater than a few centimeters).

This implies that if the force distribution $f(x, t) = \delta(x - x_0) \varphi(t)$ is assumed to represent a point-force exerted by the hammer felt at the position $x = x_0$, then the response $y(x_0, t)$ at the excitation point satisfies $\hat{y}(x_0, \omega) = 2 [g_s(\omega) + g_d(\omega)] \hat{\varphi}(\omega)$. This case is represented in Fig. 4 as a block-diagram. Similar block-diagrams are used for bowed strings (*cf. e.g.* the review article by Smith⁹, Fig. 14).

V. CONCLUSION AND PROSPECTS

The conclusion of this paper is that a complete mathematical treatment of the one-dimensional wave equation (15) carefully takes into account all the waves provided by the dispersion equation. Fast-decaying waves can be neglected in the waveguide modeling of portions of string without sources if they are long enough. However, they cannot accurately be neglected at the neighborhood of the excitation region (hammer) and of the fixation points (bridge, *capo d'astro* bar).

In particular if a point-force is exerted by the hammer felt on the string, the waveguide model proposed by Bensa *et al.* (Ref. 3, Fig. 2) needs to be complemented at the excitation point, as shown in Fig. 4 which summarizes the results of the last section. Note that a realistic excitation by the hammer is distributed over a certain width⁴. This extension could be made by a spatial convolution. A future study may determine whether or not this correction would noticeably improve the quality of synthesized stiff-string sounds.

This paper is an attempt to extract as much information as possible from the physical model defined by a one-dimensional wave equation, in a *waveguide modeling* context and from a mathematical point of view. It is hoped that this study will help to improve future waveguide models of strings and to enhance the accuracy of efficient computational models using *Digital Waveguides*^{6,7,3}, after a substantial effort to design suitable digital filters.
