# Chapter 1

## Introduction

Industrial robots were originally dedicated to “pick and place” operations. They start to be used for machining operations such as trimming, deflashing, degating, sanding and sawing. Machining robots are currently developed to help the operator realize machining operations, which have been mainly performed with Computer Numerical Control (CNC) machines so far. Industrial robots can be used, first to reduce scrap rates and production costs, and secondly to increase the volume and flexibility of production lines. However, industrial robots are not as accurate as CNC machine tools, but the total cost of a machining robot is 30% less compared with an equivalent CNC machine. Therefore, it makes sense that the larger the parts to be machined, the more interesting robot machining.

Some research works on robotic-based manufacturing have been conducted in the last two decades. The main drawback of industrial serial robots for machining operations turns to be their lack of stiffness and as a result, large manufacturing errors occur [1–3]. Indeed, a conventional machine tool is about fifty times stiffer than an industrial serial robot [2].

Matsuoka *et al.* [1] studied the robotic-based milling. They claimed that the machining quality can be improved by decreasing the cutting forces, namely, by decreasing the diameter of the tool and by increasing the spindle speed. Zhang *et al.* [2] proposed a real-time compensation of the robot end-effector displacement, based on the evaluation of each joint deflection. To this end, they wrote an elastostatic model of the robot at hand and used a wrench sensor to measure the forces and moments applied on the robot end-effector at any time. Besides, Tisius *et al.* [4] described 50 operational criteria and 50 potential criteria for serial manipulator operation, much of which applies to precision machining. Machining quality and robot energy consumption may also depend on the workpiece placement. Thus, Ur-Rehman *et al.* focused on the multiobjective path placement optimization of a parallel kinematics machine based on energy consumption, shaking forces and maximum actuator torques [5].

The vibration of the robot itself is another issue to deal with in robotic machining [3, 6].

As a matter of fact, the first natural frequency of an industrial robot is about 10 to 100 times smaller than the one of conventional machine tools [6]. Pan *et al.* also noticed that the vibrations occurring during robotic machining operations are not regenerative but structural [6]. Therefore, they came up with a stability criterion from the elastodynamic modeling of the robot and the cutting forces. Then, they formulated some rules for robotic machining from several experimental tests.

This report introduces a methodology that aims to determine the best placement of the workpiece to be machined knowing the cutting forces exerted on the tool and the elastostatic model of the robot. A machining quality criterion is proposed and an optimization problem is formulated and solved. The KUKA KR270-2 robot is used as an illustrative example throughout the report.

Section 2 presents the workpiece test and the cutting forces applied by the workpiece on the tool along the machined path. Section 3 describes the robotic cell. Section 4 deals with the formulation of a mono-objective optimization problem to find the optimum placement of the workpiece with regard to a proposed machining quality criterion. Section 5 highlights the optimum and worst workpiece placements within the robotic cell. The best and worst redundancy planning schemes associated with those placements are also determined. Section 6 is about the conclusions of the report and the future work.

## Chapter 2

# Robotic Cell and Parameterization

The robotic cell shown in Fig. 2.1 is composed of a KUKA KR270-2 robot, a FISCHER milling spindle mounted on the robot end-effector and a rotary table.

The geometric parameters of the robot are presented in [9]. An identification procedure was developed in [10] in order to determine all joint stiffness values of the KUKA KR270-2 robot. Accordingly, the translational and rotational displacements of the tool can be predicted knowing the wrench exerted on it. It is noteworthy that the flexibility of the links is considered through the identified joint stiffness values.

The FISCHER milling spindle is of type MFW 1709/24. Its maximum rotational speed is equal to 24 000 rpm and its power is equal to 20 kW.

The orientation of the workpiece can be fully represented with the variables  $(Q_2, Q_3, Q_4)$ , a subset of the quaternions coordinates. Indeed, the quaternions represent the rotations of the workpiece with a rotation axis  $\mathbf{u} = [u_x \ u_y \ u_z]^T$  and an angle  $\theta$ . The relation between the quaternions and the axis and angle representation can be found in [11]:

$$Q_1 = \cos(\theta/2) \quad (2.1)$$

$$Q_2 = u_x \sin(\theta/2) \quad (2.2)$$

$$Q_3 = u_y \sin(\theta/2) \quad (2.3)$$

$$Q_4 = u_z \sin(\theta/2) \quad (2.4)$$

where  $u_x^2 + u_y^2 + u_z^2 = 1$  and  $0 \leq \theta \leq \pi$ .

Nevertheless, the workpiece can be only rotated about the vertical axis of the robot base frame  $\mathcal{F}_0$  due to the geometry of the rotary table. Therefore,

$$Q_2 = Q_3 = 0 \quad (2.5)$$

Figure 2.1 – Robotic cell located at University of Nantes, France

and

$$-1 \leq Q_4 \leq 1 \quad (2.6)$$

Figure 2.2 – Closed loop chain and frames  $\mathcal{F}_0$ ,  $\mathcal{F}_6$ ,  $\mathcal{F}_7$  and  $\mathcal{F}_W$

Figure 2.3 – Kinematic redundancy characterized with angle  $\beta_i$

Figure 2.2 represents the closed loop chain composed of the KUKA KR270-2 robot, the FISCHER milling spindle, the workpiece and the rotary table. It also depicts the robot base

frame  $\mathcal{F}_0$ , the frame  $\mathcal{F}_6$  attached to the robot end-effector, the frame  $\mathcal{F}_7$  attached to the spindle and the workpiece frame  $\mathcal{F}_W$ . From the previous closed loop chain, we can write:

$${}^0T_W {}^WT_{P_i} = {}^0T_6 {}^6T_7 {}^7T_{P_i} \quad (2.7)$$

where

${}^0T_W$  is the homogeneous transformation matrix from frame  $\mathcal{F}_0$  to frame  $\mathcal{F}_W$  expressed as:

$${}^0T_W = \begin{bmatrix} 2Q_1^2 - 1 & -2Q_1Q_4 & 0 & {}^0x_{OW} \\ Q_1Q_4 & 2Q_1^2 - 1 & 0 & {}^0y_{OW} \\ 0 & 0 & 1 & {}^0z_{OW} \\ 0 & 0 & 0 & 1 \end{bmatrix} \quad (2.8)$$

${}^0x_{OW}$ ,  ${}^0y_{OW}$  and  ${}^0z_{OW}$  being the Cartesian coordinates of point  $O_W$  expressed in frame  $\mathcal{F}_0$ .

${}^WT_{P_i}$  is the homogeneous transformation matrix from frame  $\mathcal{F}_W$  to frame  $\mathcal{F}_{P_i}$  attached to the  $i$ th point of the tool path as shown in Fig. 3.1.

${}^0T_6$  is the homogeneous transformation matrix from frame  $\mathcal{F}_0$  to frame  $\mathcal{F}_6$ .

${}^6T_7$  is the homogeneous transformation matrix from frame  $\mathcal{F}_6$  to frame  $\mathcal{F}_7$  and depends on the geometry of the spindle and how the latter is mounted on the robot end-effector. Here,

$${}^6T_7 = \begin{bmatrix} 0 & -\sqrt{2}/2 & \sqrt{2}/2 & 0 \\ 1 & 0 & 0 & 0 \\ 0 & \sqrt{2}/2 & \sqrt{2}/2 & 0.684 \\ 0 & 0 & 0 & 1 \end{bmatrix} \quad (2.9)$$

${}^7T_{P_i}$  is the homogeneous transformation matrix from frame  $\mathcal{F}_{P_i}$  to frame  $\mathcal{F}_7$ . Note that the KUKA KR270-2 robot has six degrees of freedom, whereas the milling operation sets only five degrees of freedom as the rotation of the spindle about the tool axis is not fixed. Therefore, the robot is redundant with respect to the task and the kinematic redundancy is equal to one as explained in [12, 13]. Here, the kinematic redundancy is characterized by the angle  $\beta_i$ , which corresponds to the rotation angle of the spindle about the tool axis

at the  $i$ th point of the tool path as shown in Fig. 4.6. As a consequence,

$${}^7T_{P_i} = \begin{bmatrix} \cos(\beta_i) & \sin(\beta_i) & 0 & 0 \\ \sin(\beta_i) & -\cos(\beta_i) & 0 & 0 \\ 0 & 0 & -1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \quad (2.10)$$

## Chapter 3

# Machining Task and Cutting Force Model

### 3.1 Machining Task

Figure 3.1 illustrates the workpiece to be machined, which is made up of aluminum alloy.  $\mathcal{F}_W$  of origin  $O_W$  is the frame attached to the workpiece. The five segments  $AB$ ,  $BC$ ,  $CO_W$ ,  $O_W D$  and  $DE$ , of length equal to 200 mm each, have to be milled. The tool path is offset by the tool radius from the five segments to be milled. The tool path is discretized into  $n$  points and is shown in dashed line in Fig. 3.1. Frame  $\mathcal{F}_{P_i}$  is attached to the  $i$ th point of the tool path,  $i = 1, \dots, n$ .  $X_{P_i}$  is along the feed direction.  $Z_{P_i}$  is along the tool axis and points toward the robot.

Table 3.1 – Cutting Conditions

Spindle speed	Feed speed	$f_z$	$a_p$	$a_e$
20 000 rpm	4 m/min	0.05 mm/tooth/rev	5 mm	varies

The machining quality is affected by the robot deviation due to the cutting forces applied on the tool [7]. The cutting conditions are given in Tab. 3.1 where  $f_z$ ,  $a_p$  and  $a_e$  denote the feed rate, the depth of cut and the width of cut, respectively. The cutting forces are evaluated thanks to the cutting force model described in [8]. As a result, Fig. 3.2 depicts the force components applied by the tool on the workpiece along axes  $X_W$ ,  $Y_W$  and  $Z_W$  of frame  $\mathcal{F}_W$  as a function of the tool path point number.

### 3.2 Cutting Force Model

The tool is composed of several teeth. We consider in this report a tool composed of four teeth. Figure 3.3 presents the chip and the directions of the tangential force  $F_t$  and the radial force  $F_r$ .

Material to remove

Tool path

Final piece

Tool

Figure 3.1 – Workpiece

Figure 3.2 – Force components applied by the tool on the workpiece expressed in frame  $\mathcal{F}_W$  as a function of the tool path point number

applied by each tooth on the workpiece.

Figure 3.3 – Chip geometry and definition of  $\varphi_{in}$  and  $\varphi_{out}$

The instantaneous forces exerted by the tooth on the workpiece are defined in [8] and are expressed as follows:

$$\begin{aligned}\delta F_t &= K_t a_p f_z \sin(\varphi) d\varphi \\ \delta F_r &= K_r \|\delta F_t\|\end{aligned}\quad (3.1)$$

The mean forces  $F_x$  and  $F_y$  along the  $x$  and  $y$  axes associated with one tooth are expressed as:

$$\begin{aligned}F_x &= \int_{\varphi_{out}}^{\varphi_{in}} (\|F_t\| \cos(\varphi) + \|F_r\| \sin(\varphi)) d\varphi \\ F_y &= \int_{\varphi_{out}}^{\varphi_{in}} (-\|F_t\| \sin(\varphi) + \|F_r\| \cos(\varphi)) d\varphi\end{aligned}\quad (3.2)$$

Therefore, if  $\varphi \in [\varphi_{in} \varphi_{out}]$ ,

$$\begin{aligned}F_x &= K_t a_p f_z \left( -\frac{\cos(2\varphi_{out})}{4} + K_r \frac{\varphi_{out}}{2} - K_r \frac{\sin(2\varphi_{out})}{4} \right) + \\ &\quad K_t a_p f_z \left( \frac{\cos(2\varphi_{in})}{4} - K_r \frac{\varphi_{in}}{2} + K_r \frac{\sin(2\varphi_{in})}{4} \right) \\ F_y &= K_t a_p f_z \left( \frac{\sin(2\varphi_{out})}{4} - \frac{\varphi_{out}}{2} - K_r \frac{\cos(2\varphi_{out})}{4} \right) + \\ &\quad K_t a_p f_z \left( -\frac{\sin(2\varphi_{in})}{4} + \frac{\varphi_{in}}{2} + K_r \frac{\cos(2\varphi_{in})}{4} \right)\end{aligned}\quad (3.3)$$

else,

$$\begin{aligned}F_x &= 0 \\ F_y &= 0\end{aligned}\quad (3.4)$$

$f_z$  is the feed rate and  $a_p$  is the depth of cut. Then, the global cutting force exerted by the

entire tool on the piece can be calculated. Coefficients  $K_t$  and  $K_r$  were determined from cutting experiments with a force measurement system.

## Chapter 4

# Experimentations

### 4.1 Identification of the Joint Stiffness Values

The translational and rotational displacements of the robot end-effector can be evaluated if the forces and moments applied on it are known. To this end, the stiffness model of the robot defined by Eq. (4.1) was determined based on the CCT Theory [16]. The links of the robot are supposed to be quite stiffer than the joints and not known as it happens usually for industrial robots [17]. Then, the relationship between the wrench applied on the robot end-effector and its small displacement screw is defined as follows:

$$\mathbf{w} = \mathbf{K}_X \delta \mathbf{X} \quad (4.1)$$

where  $\mathbf{K}_X$  is the Cartesian stiffness matrix of the robot.  $\mathbf{w}$  is the 6-dimensional vector of forces and moments exerted on the robot end-effector and derived from Sec. 3.2.  $\delta \mathbf{X}$  is the obtained 6-dimensional small displacement screw of the end-effector.

The Cartesian stiffness matrix  $\mathbf{K}_X$  that depends on the robot configuration, the joint stiffness values and the wrench applied on the end-effector takes the form:

$$\mathbf{K}_X = \mathbf{J}^{-T} (\mathbf{K}_\theta - \mathbf{K}_C) \mathbf{J}^{-1} \quad (4.2)$$

Figure 4.1 – Experimental setup for the joint stiffness identification of the KUKA KR270-2 robot

with

$$\mathbf{K}_\theta = \begin{bmatrix} k_{\theta_1} & 0 & 0 & 0 & 0 & 0 \\ 0 & k_{\theta_2} & 0 & 0 & 0 & 0 \\ 0 & 0 & k_{\theta_3} & 0 & 0 & 0 \\ 0 & 0 & 0 & k_{\theta_4} & 0 & 0 \\ 0 & 0 & 0 & 0 & k_{\theta_5} & 0 \\ 0 & 0 & 0 & 0 & 0 & k_{\theta_6} \end{bmatrix} \quad (4.3)$$

and

$$\mathbf{K}_C = \begin{bmatrix} \frac{\partial \mathbf{J}^T}{\partial \theta_1} \mathbf{w} & \frac{\partial \mathbf{J}^T}{\partial \theta_2} \mathbf{w} & \frac{\partial \mathbf{J}^T}{\partial \theta_3} \mathbf{w} & \frac{\partial \mathbf{J}^T}{\partial \theta_4} \mathbf{w} & \frac{\partial \mathbf{J}^T}{\partial \theta_5} \mathbf{w} & \frac{\partial \mathbf{J}^T}{\partial \theta_6} \mathbf{w} \end{bmatrix} \quad (4.4)$$

$\mathbf{J}$  is the kinematic Jacobian matrix of the robot.  $\mathbf{K}_\theta$  is its diagonal joint stiffness matrix and  $\mathbf{K}_C$  is the complementary stiffness matrix, which depends on the wrench applied on the end-effector.

Table 4.1 – Apparent joint stiffness values in [MNm/rad] of the KUKA KR270-2 robot

$k_{\theta_1}$	$k_{\theta_2}$	$k_{\theta_3}$	$k_{\theta_4}$	$k_{\theta_5}$	$k_{\theta_6}$
0.237	3.32	2.79	0.486	0.521	0.38

An identification procedure was developed in [10] in order to determine all joint stiffness values of the robot. Accordingly, the translational and rotational displacements of the end-effector can be predicted knowing the wrench exerted on it. It is noteworthy that the flexibility of the links is considered through the identified joint stiffness values. The joint stiffness values of the KUKA KR270-2 robot are given in Table 4.1. They were obtained by using the experimental setup shown in Fig. 4.1 and described in [9,18].

## 4.2 Influence of the Workpiece Placement and the Kinematic Redundancy on the Machining Quality

This section aims to show the influence of the workpiece placement and the kinematic redundancy on the machining quality of a test workpiece through some experimental results.

### 4.2.1 Evaluation of the tool displacement during a milling operation

Knowing the joint stiffness values of the robot from Sec. 4.1 and the forces exerted on the robot end-effector from Sec. 3.2, it is possible to predict the tool displacement using the stiffness

matrix defined with Eq. (4.1). Four machining operations were realized in order to validate

Table 4.2 – Cutting conditions

Reference	$N$ [tr/min]	$a_p$ [mm]	$V_f$ [mm/min]
P3	20 000	5	3 600
P4	10 000	5	3 600
P5	6 670	5	3 600

the theoretical elastostatic model of the KUKA KR270-2 robot: (i) a workpiece made up of a resin material called LAB was milled along a 300 mm linear path. It is noteworthy that the LAB material exerts a small force on the tool; (ii) a workpiece made up of an Aluminium alloy was milled along a 300 mm linear path with the cutting conditions P3 given in Table 4.2; (iii) a workpiece made up of an Aluminium alloy was milled along a 300 mm linear path with the cutting conditions P4 given in Table 4.2; (iv) a workpiece made up of an Aluminium alloy was milled along a 300 mm linear path with the cutting conditions P5 given in Table 4.2.  $N$ ,  $a_p$  and  $V_f$  denote the rotational speed of the tool, the depth of cut and the feed speed, respectively.

Figure 4.2 – Calculated and measured paths associated with four milling conditions

Figure 4.2 illustrates the corresponding measured and calculated paths. The inherent straightness of the robot explains the difference between the calculated and measured paths in the LAB material. We can notice that the difference between the calculated and measured

paths for the other machining operations is about 5% and is also partly due to the inherent straightness of the robot. Consequently, it is possible to evaluate the path that will be followed by the tool considering its displacement due to the cutting forces from the elastostatic model of the robot defined with Eq. (4.1).

#### 4.2.2 Influence of the task placement on the machining quality

Figure 4.3 – Test workpiece

In order to show the influence of the task placement on the machining quality, a test workpiece shown in Fig. 4.3 was milled in two different placements within the robot Cartesian workspace. The two placements of the test workpiece are illustrated in Fig. 4.4. Four machining operations were realized with the same cutting condition, namely, the cutting condition P4 described in Table 4.2: (i) the milling of the test workpiece made up of a LAB material located in Placement 1; (ii) the milling of the test workpiece made up of an Aluminium alloy located in Placement 1; (iii) the milling of the test workpiece made up of a LAB material located in Placement 2; (iv) the milling of the test workpiece made up of an Aluminium alloy located in Placement 2.

Figure 4.5 shows the measures of the four resulting workpieces, namely, the milling quality of the four resulting workpieces. It is apparent that the resulting workpieces made up of a LAB material are closed to the desired workpiece represented with the black straight line in Fig. 4.5, while there is a non negligible gap between the resulting workpieces made up of an Aluminium alloy and the desired workpiece. Moreover, the difference between the two

Figure 4.4 – Two placements of the test workpiece

Figure 4.5 – Measurement of the test workpiece milled in two different placements

resulting workpieces made up of an Aluminium alloy is important. As a consequence, we can claim that the placement of the workpiece really affects its milling quality.

### 4.2.3 Influence of the kinematic redundancy on the machining quality

The KUKA KR270-2 robot has six degrees of freedom. The milling operations sets only five degrees of freedom because the rotation of the spindle about the tool axis is not fixed. Therefore, the robot is redundant with respect to the task, the robot redundancy being equal to one as explained in [12,13]. Here, the robot redundancy is characterized by the angle  $\beta$ , which denotes the rotation angle of the spindle about the tool axis and is depicted in Fig. 4.6. Figure 4.7 illustrates the quality of two test workpieces made up of an aluminium alloy and milled in the same placement, but with two different redundancy planning schemes. It is apparent that the milling quality also depends on the redundancy planning scheme chosen for the machining operation.

Figure 4.6 – Kinematic redundancy characterized with angle  $\beta$

Figure 4.7 – Quality of the test workpiece milled in a given placement, but with two different redundancy planning schemes

## Chapter 5

# Optimum Workpiece Placement

This section deals with a methodology that aims to determine the best placement of the workpiece to be machined knowing the cutting forces exerted on the tool and the elastostatic model of the robot. The proposed methodology is highlighted through the definition of a machining quality criterion and the formulation of a mono-objective optimization problem.

### 5.1 Machining quality criterion

It makes sense that the tool displacement  $c_i$ , normal to both the feed direction along axis  $X_{Pi}$  and the tool axis  $Z_7$ , is mainly responsible for machining errors.  ${}^0\mathbf{x}_{Pi}$  and  ${}^0\mathbf{z}_7$  are the unit vectors of axes  $X_{Pi}$  and  $Z_7$  expressed in frame  $\mathcal{F}_0$ , respectively.  $c_i$  can be expressed as follows:

$$c_i = \left| {}^0\delta\mathbf{d}_i^T \left( {}^0\mathbf{z}_7 \times {}^0\mathbf{x}_{Pi} \right) \right| \quad (5.1)$$

where  ${}^0\delta\mathbf{d}_i$  is the point-displacement of the tool at the  $i$ th point of the tool path expressed in frame  $\mathcal{F}_0$  and  $\times$  denotes the cross product. The point-displacement  ${}^0\delta\mathbf{d}_i$  is evaluated thanks to the Cartesian stiffness matrix  $\mathbf{K}$  of the KUKA KR270-2 robot obtained in [9] and from the wrench  $\mathbf{w}$  applied by the tool on the workpiece that are depicted in Fig. 3.2, namely,

$${}^0\delta\mathbf{d}_i = \mathbf{K}^{-1} \mathbf{w} \quad (5.2)$$

The machining quality criterion  $f_{MQC}$ , which is the objective function of the optimization problem at hand, is defined as the mean of  $c_i$  values, namely,

$$f_{MQC} = \frac{1}{n} \sum_{i=1}^n c_i \rightarrow \min \quad (5.3)$$

The smaller  $f_{MQC}$ , the better the machining quality.

## 5.2 Decision variables

The decision variable vector of the optimization problem at hand contains the Cartesian coordinates of point  $O_W$  expressed in frame  $\mathcal{F}_0$ , i.e.,  ${}^0x_{OW}$ ,  ${}^0y_{OW}$  and  ${}^0z_{OW}$  and the orientation parameter  $Q_4$  of the workpiece.

The decision variable vector also contains the redundancy planning scheme. Let  $\beta_i$  be the rotation angle of the spindle about the tool axis at the  $i$ th point of the discretized tool path as shown in Fig. 4.6. Accordingly, the redundancy planning scheme is defined by vector  $\beta$  expressed as:

$$\beta = \begin{bmatrix} \beta_1 & \beta_2 & \cdots & \beta_n \end{bmatrix}^T \quad (5.4)$$

with  $-\pi \leq \beta_i \leq \pi, i = 1, \dots, n$ .

The KUKA KR270-2 robot may have eight solutions to the inverse geometric model, namely, eight postures. The robot has to keep the same posture along a given segment in order to avoid signs of wear. However, the robot posture can change from one segment to the next one.  $\mu_j$  denotes the solution number to the inverse geometric model of the robot along the  $j$ th segment of the tool path,  $j = 1, \dots, 5$ . As a consequence, the posture scheme is defined by vector  $\mu$  expressed as:

$$\mu = \begin{bmatrix} \mu_1 & \mu_2 & \mu_3 & \mu_4 & \mu_5 \end{bmatrix}^T \quad (5.5)$$

with  $\mu_j \in [1, \dots, 8]$ .

## 5.3 Constraints

Four types of constraints arise in the optimization problem at hand:

1. The joint angles of the KUKA KR270-2 robot should be bounded between its joint limits,

$$-185 \text{ deg} \leq \theta_{1i} \leq 185 \text{ deg} \quad (5.6)$$

$$0 \leq \theta_{2i} \leq 146 \text{ deg} \quad (5.7)$$

$$-245 \text{ deg} \leq \theta_{3i} \leq 29 \text{ deg} \quad (5.8)$$

$$-350 \text{ deg} \leq \theta_{4i} \leq 350 \text{ deg} \quad (5.9)$$

$$-125 \text{ deg} \leq \theta_{5i} \leq 125 \text{ deg} \quad (5.10)$$

$$-350 \text{ deg} \leq \theta_{6i} \leq 350 \text{ deg} \quad (5.11)$$

$\theta_{ji}$  being the  $j$ th joint angle of the robot,  $j = 1, \dots, 6$ , when the tool is located at the  $i$ th point of the tool path,  $i = 1, \dots, n$ . Note that the robot was parameterized by using the modified Denavit-Hartenberg convention [11].

2. The tool displacement  $c_i$  expressed with (5.1) should be smaller than a given value  $c_{max}$ , which is defined with regard to the expected machining quality, i.e.,

$$\max(|c_1|, |c_2|, \dots, |c_n|) \leq c_{max} \quad (5.12)$$

where  $|\cdot|$  denotes the absolute value.

3. The workpiece should be located within a work volume that depends on the rotary table size and location within the robotic cell. Here,

$$x_{min} \leq^0 x_{OW} \leq x_{max} \quad (5.13)$$

$$y_{min} \leq^0 y_{OW} \leq y_{max} \quad (5.14)$$

$$z_{min} \leq^0 z_{OW} \leq z_{max} \quad (5.15)$$

with  $x_{min} = -0.3$  m,  $x_{max} = 0.3$  m,  $y_{min} = -2.24$  m,  $y_{max} = -1.64$  m,  $z_{min} = -0.602$  m and  $z_{max} = -0.214$  m.

4. The robot should be far from singularities while the tool follows the path, namely,

$$1/\kappa_F(\mathbf{J}_{Ni}) > 0.2, \quad i = 1, \dots, n \quad (5.16)$$

where  $\mathbf{J}_{Ni}$  is the normalized kinematic Jacobian matrix of the KUKA KR270-2 robot defined in [9] and evaluated at the  $i$ th point of the tool path.  $\kappa_F(\mathbf{J}_{Ni})$  is condition number of matrix  $\mathbf{J}_{Ni}$  based on the Frobenius norm.

## 5.4 Formulation of the optimization problem

From (5.3) to (5.16), the optimization problem to solve in order to find the best workpiece placement can be formulated as follows:

$$\begin{aligned}
 &\text{minimize} && f_{MQC} \\
 &\text{over} && \mathbf{x} = \left[ {}^0x_{OW} \ {}^0y_{OW} \ {}^0z_{OW} \ Q_4 \ \boldsymbol{\beta}^T \ \boldsymbol{\mu}^T \right]^T \\
 &\text{subject to} && \max(|c_1|, |c_2|, \dots, |c_n|) \leq c_{max} \\
 &&& -185 \text{ deg} \leq \theta_{1i} \leq 185 \text{ deg} \\
 &&& 0 \leq \theta_{2i} \leq 146 \text{ deg} \\
 &&& -245 \text{ deg} \leq \theta_{3i} \leq 29 \text{ deg} \\
 &&& -350 \text{ deg} \leq \theta_{4i} \leq 350 \text{ deg} \\
 &&& -125 \text{ deg} \leq \theta_{5i} \leq 125 \text{ deg} \\
 &&& -350 \text{ deg} \leq \theta_{6i} \leq 350 \text{ deg} \\
 &&& 1/\kappa_F(\mathbf{J}_{Ni}) > 0.2 \\
 &&& x_{min} \leq {}^0x_{OW} \leq x_{max} \\
 &&& y_{min} \leq {}^0y_{OW} \leq y_{max} \\
 &&& z_{min} \leq {}^0z_{OW} \leq z_{max} \\
 &&& -1 \leq Q_4 \leq 1 \\
 &&& i = 1, \dots, n
 \end{aligned} \tag{5.17}$$

Optimization problem (5.17) aims to find the optimum workpiece placement and the corresponding optimum redundancy planning scheme that minimize the machining quality criterion  $f_{MQC}$  defined by (5.3) while respecting the set of constraints.

## 5.5 Result Analysis

A hybrid optimization algorithm was used to solve optimization problem (5.17). As a matter of fact, a genetic algorithm [14] was used to find the initial guess of an interior-point algorithm for large-scale nonlinear programming [15]. The Matlab *ga* function combined with the Matlab *fmincon* function were used.

The genetic algorithm converged after 51 generations as shown in Fig. 5.1, each population containing 120 individuals. Then, a local optimum decision variable vector  $\mathbf{x}_{opt}$  of optimization

Figure 5.1 – Convergence of the genetic algorithm for the determination of the best workpiece placement

problem (5.17) was obtained with the Matlab *fmincon* function and is expressed as:

$$\mathbf{x}_{opt} = \begin{bmatrix} 0.0022 & -1.6435 & -0.5564 & 0.9258 & \beta_{opt} & \mu_{opt} \end{bmatrix}^T \quad (5.18)$$

with  $\mu_{opt} = \begin{bmatrix} 4 & 4 & 4 & 5 & 5 \end{bmatrix}^T$  meaning that the robot posture changes between segment 3 and

Figure 5.2 – Tool displacement  $c_i$  [m] as a function of the tool path point number and  $\beta$  angle for the best workpiece placement. The green curve characterizes the optimum redundancy planning scheme, i.e.,  $\beta_{opt}$  vector, whereas the red curve represents the worst redundancy planning scheme for this workpiece placement

Figure 5.2 illustrates the tool displacement  $c_i$  with respect to the tool path point number and  $\beta$  angle for the optimal workpiece placement. The green curve characterizes the optimum redundancy planning scheme, i.e.,  $\beta_{opt}$  vector, whereas the red curve represents the worst redundancy planning scheme for this workpiece placement. The white areas can not be reached by the robot because of its joint limits.

It is noteworthy that  ${}^0x_{OW}$ ,  ${}^0y_{OW}$ ,  ${}^0z_{OW}$ ,  $Q_4$  and  $\mu$  are the only decision variables considered by the *ga* and *fmincon* functions in this optimization problem solving. As a matter of fact, an optimal  $\beta$  vector is searched at each iteration of the genetic algorithm and at each iteration of the interior-point algorithm. This vector is obtained in such a way that it minimizes the objective function  $f_{MQC}$  and avoids discontinuities in the robot joint space along each segment.

Figure 5.3 – Optimum workpiece placement

Figure 5.3 represents the optimum workpiece placement found by solving optimization problem (5.17).

It is noteworthy that the worst workpiece placement is obtained by maximizing the objective function  $f_{MOC}$  while respecting the constraints of optimization problem (5.17).

Figure 5.4 – Tool displacement  $c_i$  [m] as a function of the tool path point number and  $\beta$  angle for the worst workpiece placement. The green curve characterizes the optimum redundancy planning scheme, whereas the red curve represents the worst redundancy planning scheme for this workpiece placement

Figure 5.4 illustrates the tool displacement  $c_i$  with respect to the tool path point number and  $\beta$  angle for the worst workpiece placement. The green curve characterizes the optimum redundancy planning scheme, i.e.,  $\beta_{opt}$  vector, whereas the red curve represents the worst redundancy planning scheme for this workpiece placement.

Let us compare the machining quality of the workpiece obtained with the four following milling conditions:

**Case 1:** Optimum workpiece placement with the best redundancy planning scheme (see Fig. 5.2)

**Case 2:** Optimum workpiece placement with the worst redundancy planning scheme (see Fig. 5.2)

**Case 3:** Worst workpiece placement with the best redundancy planning scheme (see Fig. 5.4)

**Case 4:** Worst workpiece placement with the worst redundancy planning scheme (see Fig. 5.4)

An video of the milling operation corresponding to Case 1 can be downloaded at<sup>1</sup>. An video of the milling operation corresponding to Case 2 can be downloaded at<sup>2</sup>. An video of the milling operation corresponding to Case 3 can be downloaded at<sup>3</sup>. An video of the milling operation corresponding to Case 4 can be downloaded at<sup>4 5</sup>.

Table 5.1 – Machining Quality Criterion for Four Milling Conditions

	Case 1	Case 2	Case 3	Case 4
$f_{MQC}$ [mm]	0.083	0.35	0.82	1.2

Table 5.1 gives the values of the machining quality criterion  $f_{MQC}$  defined in (5.3) for the previous four milling conditions. It is apparent that both the workpiece placement and the kinematic redundancy affect the machining quality of the workpiece. Table 5.1 shows that it is important to pay attention to the workpiece placement and kinematic redundancy. Indeed,  $f_{MQC}$  value for Case 4 is more than 14 times higher than  $f_{MQC}$  value for Case 1.

## Chapter 6

# Conclusions and Future Work

This report introduced a methodology to determine the optimum placement of any workpiece to be machined knowing the cutting forces exerted on the tool and the elastostatic model of the KUKA KR270-2 robot. First, a workpiece test was introduced and the forces applied by the workpiece to the tool were evaluated by using an existing cutting force model. Then, the robotic cell was presented. It contains a KUKA KR270-2 robot, a FISCHER milling spindle and a rotary table. The parameterization of the closed loop chain composed of the foregoing components and the workpiece was also described. A machining quality criterion was introduced and a mono-objective optimization problem was formulated in order to determine the optimum placement of a workpiece to be machined and the associated best redundancy planning scheme. The worst workpiece placement and the associated worst redundancy planning were also obtained by maximizing the objective function of the optimization problem at hand. It is noteworthy that the machining quality criterion corresponding to the optimum workpiece placement and the associated best redundancy planning scheme is more than 14 times smaller than the machining quality criterion corresponding to the worst workpiece placement and the associated worst redundancy planning scheme. Therefore, it is important to pay attention to the workpiece placement and kinematic redundancy for machining operations with a KUKA KR270-2 robot.

The theoretical results presented in this report will be checked experimentally soon. The extension of the proposed methodology to robot machining operations with a higher kinematic redundancy of the robot with regard to the task, such as a machining robot mounted on a rail or a mobile platform, are also part of the future work.
