Abstract—This paper deals with the speed control of a Permanent Magnet Synchronous Generator (PMSG)-based Marine Current Turbine (MCT). Indeed, to increase the generated power and therefore the efficiency of an MCT, a nonlinear controller has been proposed. PMSG has been already considered for similar applications particularly wind turbine systems using mainly PI controllers. However, such kinds of controllers do not adequately handle some of tidal resource characteristics such as turbulence and swell effects. Indeed, these may decrease the MCT performances. Moreover, PMSG parameter variations should be accounted for. Therefore, a robust nonlinear control strategy, namely high-order sliding mode control, is proposed. The proposed control strategy is inserted in a global simulation tool that accounts for the resource and the marine turbine models. Simulations using tidal current data from the Raz de Sein (Brittany, France), and experiments on a 7.5-kW real-time simulator are carried out for validation purposes.

Index Terms—Marine current turbine, Permanent magnet synchronous generator, modeling, nonlinear control, high-order sliding mode.

NOMENCLATURE

- PMSG = Permanent Magnet Synchronous Generator;
- MCT = Marine Current Turbine;
- HOSM = High-Order Sliding Mode;
- ρ = Fluid density;
- A = Cross-sectional area of the marine turbine;
- V_{tid} = Tidal speed;
- C_p = Power coefficient;
- C = Tide coefficient;
- V_u (V_{an}) = Spring (neap) tide current speed;
- s, (r) = Stator (rotor) index;
- d, q = Synchronous reference frame index;
- V (I) = Voltage (Current);
- P (Q) = Active (Reactive) power;
- φ = Flux;
- \phi = Permanent magnet flux;
- T_e = Electromagnetic torque (Mechanical torque);
- R = Resistance;
- L = Inductance;
- \omega = Electrical angular speed;
- f = Viscosity coefficient;
- J = Turbine rotor inertia;
- p = Pole pair number.

I. INTRODUCTION

There are basically two ways of generating electricity from marine and tidal currents: by building a tidal barrage across an estuary or a bay in high tide areas, or by extracting energy from free flowing water (tidal kinetic energy). Within the last few decades, developers have shifted towards technologies that capture tidally-driven coastal currents or tidal stream [1]. The astronomical nature of this resource makes it predictable, to within 98% accuracy for decades, and independent of prevailing weather conditions. This predictability is critical to a successful integration of renewable energy in the electrical grid [2]. It is therefore obvious that there is a need to quantify the potential to generating electricity from these various sites [3]. In this context, and in previous works, different control strategies of control mainly for Doubly-Fed Induction Generator- (DFIG) based marine current turbines have been tested to evaluate the generated power [4-6].

In this paper, and in order to be able to compare and choose the adequate technology, a robust nonlinear control of a PMSG-based marine current turbine is carried out [7]. The adopted control strategy, namely high-order sliding mode (HOSM), relies on the resource and the marine turbine models that were validated by experimental data [8]. Simulations, using tidal current data from the Raz de Sein (Brittany, France), and experiments on a 7.5-kW real-time simulator are carried out for validation purposes.

II. MARINE CURRENT TURBINE MODELING [8]

The global scheme for a grid-connected marine current turbine is given by Fig. 1.

A. The Resource Model

1) Resource Potential. The total kinetic power in a marine current turbine has a similar dependence to that of a wind turbine and is governed by the following equation [9].
The harnessing of the energy in a tidal flow requires the conversion of kinetic energy in a moving fluid, in this case water, into the motion of a mechanical system, which can then drive a generator. It is not too surprising, therefore, that many developers suggest using technology that mirrors that which has been successfully utilized to harness the wind, which is also a moving fluid [1]. Moreover, much of the technology is based upon the use of horizontal axis turbines, such as that shown in Fig. 3. Therefore, much can be transferred from the modeling and operation of wind turbines. There are, however, a number of fundamental differences in the design and operation of marine turbines. Particular differences entail changes in force loadings, immersion depth, different stall characteristics, and the possible occurrence of cavitation [11].

The Blade Element Momentum (BEM) theory method has therefore been used for the marine turbine rotor modeling. Indeed, it is widely used in the industry as a computational tool to predict aerodynamic loads and power of turbine rotors [12]. It is relatively simple and computationally fast meeting the requirements of accuracy and control loop computational speed.

C. The PMSG Model

The generator chosen for the marine current system was the PMSG [13-15]. Indeed, the benefit of using a PMSG in renewable energy applications as an alternative to conventional generators is its higher efficiency. Moreover, the elimination of the gearbox and the introduction of variable speed control would further increase the availability of the system; reduce its active weight, and the need for maintenance. A schematic diagram of a PMSG-based generation system is shown in Fig. 4.

The PMSG dynamic equations are expressed in the $d$-$q$ reference frame. The model of electrical dynamics in terms of voltage and current can be given as (4) [16]

\[
\begin{align*}
\frac{dI_d}{dt} &= -\omega L_q I_q - \omega L_d I_d - RI_d + L_s \frac{dI_q}{dt} \\
\frac{dI_q}{dt} &= -\omega L_d I_d + \omega L_q I_q - RI_q + L_s \frac{dI_d}{dt} 
\end{align*}
\]

(4)
The electromagnetic torque in the rotor is written as

\[ T_{em} = \frac{3}{2} p \left( (L_d - L_q) I_d I_q - \Phi_I I_q \right) \]  

(5)

III. CONTROL OF THE PMSG-BASED MARINE CURRENT TURBINE

A. Problem Formulation

A common practice in addressing PMSG control problem is to use a linearization approach [14], [16]. However, due to the tidal resource characteristics such as turbulence and swell effects and the inevitable uncertainties inherent in PMSG-based marine current turbines, such control methods come at the price of poor system performance and low reliability [17]. Hence the need for nonlinear and robust control to take into account these control problems. Although many modern techniques can be used for this purpose, sliding mode control has proved to be especially appropriate for nonlinear systems, presenting robust features with respect to system parameter uncertainties and external disturbances [18-21].

In particular, high-order sliding mode is especially appropriate to obtain simple control algorithms with extra features that are the elimination of the chattering phenomenon (main drawback of the traditional sliding mode approach) and a finite reaching time [22-23]. Up to now, a few second-order sliding mode control approaches have been introduced for wind and marine applications [4], [24-25].

B. Second-Order Sliding Mode Control Approach

As the chattering phenomenon is the major drawback of practical implementation of sliding mode control, the most efficient ways to cope with this problem is higher order sliding mode. This technique generalizes the basic sliding mode idea by acting on the higher order time derivatives of the sliding manifold, instead of influencing the first time derivative as it is the case in the standard (first order) sliding mode. This operational feature allows to completely mitigating the chattering effect, keeping the main properties of the original approach [24].

The proposed control strategy is based on a step-by-step procedure: First, the speed reference \( \omega_{ref} \) is generated by a Maximum Power Point Tracking (MPPT) strategy [5]. Then, an optimal electromagnetic torque, which ensures the rotor speed convergence to \( \omega_{ref} \) is computed using the following equation.

\[ T_{em\_ref} = T_m + f(\omega - \alpha(\omega - \omega_{ref}) + J\dot{\omega}_{ref} \]  

(6)

where \( \alpha \) is a positive constant. Afterwards, current references are derived to ensure the PMSG torque convergence to the optimal torque.

\[ \begin{cases} I_d\_ref = 0 \\ I_q\_ref = \frac{2}{3} \frac{T_{em}}{p\Phi_I} \end{cases} \]  

(7)

In order to ensure the currents convergence to their references, a second-order sliding mode strategy is used. Let us define the following sliding surfaces.

\[ \begin{cases} S_1 = I_d - I_{d\_ref} \\ S_2 = I_q - I_{q\_ref} \end{cases} \]  

(8)

It follows that

\[ \begin{cases} \dot{S}_1 = I_d - I_{d\_ref} \\ \dot{S}_2 = \varphi_1(t,x) + \gamma_1(t,x)V_d \end{cases} \]  

(9)

and

\[ \begin{cases} \dot{S}_1 = I_d - I_{d\_ref} \\ \dot{S}_2 = \varphi_2(t,x) + \gamma_2(t,x)V_q \end{cases} \]  

(10)

Where \( \varphi_1(t,x) \), \( \varphi_2(t,x) \), \( \gamma_1(t,x) \), and \( \gamma_2(t,x) \) are uncertain bounded functions that satisfy

\[ \begin{cases} \varphi_1 > 0, & |\varphi_1| > \Phi_1, & 0 < \Gamma_{\varphi_1} < \Gamma_{\Phi_1} \\ \varphi_2 > 0, & |\varphi_2| > \Phi_2, & 0 < \Gamma_{\varphi_2} < \Gamma_{\Phi_2} \end{cases} \]

The proposed control approach has been designed using the supertwisting algorithm that has the additional advantage of only requiring information of the sliding variable, but not of its derivative [22]. The proposed second-order sliding mode controller contains two parts:

\[ \begin{cases} V_d = u_1 + u_2 \\ V_q = w_1 + w_2 \end{cases} \]  

(11)

where

\[ \begin{cases} \dot{u}_1 = -\alpha_1 \text{sign}(S_1) \\ \dot{u}_2 = -\beta_1 |S_1| \text{sign}(S_1) \end{cases} \]  

and

\[ \begin{cases} \dot{w}_1 = -\alpha_2 \text{sign}(S_2) \\ \dot{w}_2 = -\beta_2 |S_2| \text{sign}(S_2) \end{cases} \]
In order to ensure the convergence of the sliding manifolds to zero in finite time, the gains can be chosen as follows [23].

\[
\begin{align*}
\alpha_i &> \frac{\Phi_i}{\Gamma_m} \\
\beta_i^2 &\geq \frac{4\Phi_i}{\Gamma_m} \left(\alpha_i + \Phi_i\right); i = 1, 2 \\
0 &< \rho \leq 0.5
\end{align*}
\]

The above proposed second-order sliding mode control strategy for a PMSG-based marine current turbine is illustrated by the block diagram in Fig. 5.

Finally and as an additional justification of such an advanced controller, it should be noted that its practical implementation implies an online computational cost similar to that of PI or PID controllers [24].

IV. VALIDATION RESULTS

A. Validation Using the Developed Simulation Tool

1) Validation Data and Parameters. In this work, the Raz de Sein site was chosen above several others listed in the European Commission report EUR16683 [34] due to the presence of high speed current coupled with appropriate depths suitable for marine turbine. Moreover, the marine current speed distribution for most of the time is greater than the minimum, estimated to be 1 m/sec, required for economic deployment of marine turbine.

The turbine rotor model was validated through the comparison of the simulation model with experimental data from the available literature [8] (Fig. 6). The adopted marine current turbine is of 1.44 m diameter rated at 7.5-kW. In this context, the obtained power coefficient \( C_p \) and the extractable power curves are shown by Fig. 7.

The 7.5-kW PMSG parameters are given in the appendix.

2) Simulations. In this case, the marine current turbine is simulated considering a resource first-order model (3). Therefore, for speed references given by Fig. 8 (MPPT) and a resource illustrated by Fig. 9, the PMSG-based MCT control performances are shown in Figs. 10, 11 and 12 respectively illustrating the current, the rotor speed, and the generated power.

The obtained results show good tracking performances of the PMSG current and rotor speed. Moreover, regarding [5] and as expected, the generated power is smoothest.

Fig. 6. The tested marine turbine [27].

(a) \( C_p(\lambda, \nu) \) curves. (b) The extractable power \( P(\omega, \nu) \).

Fig. 7.

Fig. 5. The proposed control structure.
B. Experimental Tests

For experimental validation of the proposed second-order sliding mode control approach, experiments were carried out using the Grenoble Institute of Technology, France (G2ELAB) renewable energy test bench.

1) The test bench [18]. The test bench presented in Fig. 13 allows the physical simulation of the marine power system. The MCT is emulated by a DC motor, which reproduces the torque and the inertia with respect to tidal speeds. The DC motor is coupled to a 7.5-kW PMSG (Appendix).

2) Experimental tests. The experimental tests were carried out as close as possible to the simulation conditions for the marine current turbine of Fig. 6. In these conditions, Figs. 14 to 15 show experimental control performances of the emulated PMSG-based MCT. These results, as in simulations, show very good tracking performances in terms of the PMSG current and rotor speed. Moreover, for comparison purposes, Fig. 16 shows simulation versus experimental results of the generated power. The obtained results are quite satisfactory as it is obvious that it is not possible to exactly emulate the marine turbine behavior. The test bench is equipped with current and torque limitations that explain some of Fig. 16 differences, in particular for high power generation. Moreover, the MCT hydrodynamic model uses torque limitations that justify a purely positive generated power in simulation [8].

V. CONCLUSIONS

This paper dealt with a second-order sliding mode control of PMSG-based marine current turbine. The proposed control strategy relies on the resource and the marine turbine models.
Its main features are a chattering-free behavior, a finite reaching time, and robustness with respect to external disturbances (e.g. grid) and unmodeled dynamics.

Tidal current data from the Raz de Sein (Brittany, France) have been used to run simulations of a 7.5-kW prototype over various flow regimes and experimental test have been carried out on a 7.5-kW PMSG test bench. The obtained results are satisfactory and very encouraging. Moreover, the experimental tests have shown that the practical implementation of the proposed second-order sliding mode controller implies an online computational cost similar to that of PI or PID controllers.

**APPENDIX**

**PARAMETERS OF THE SIMULATED AND TESTED PMSG**

\[
R = 0.173 \text{ m} \Omega, \quad L_s = 0.085 \text{ mH}, \quad L_r = 0.951 \text{ mH}, \quad \phi = 0.112 \text{ Wb} \\
J = 0.0048 \text{ kg m}^2, \quad f = 8.5 \times 10^3 \text{ Nms}^2
\]
